

Crosspod

One confirmed record of every order a small supplier receives, built from the PDFs and WhatsApp messages it already gets.

CS3216 · Group [N] · Pitch for the coolness points · September 2026

77,600	1.66 M	14.5%	2
Singapore companies, S\$1M–S\$100M	people they employ	SME AI adoption (IMDA)	suppliers in pilot talks, first demo Monday

THE PROBLEM

A machining supplier, Woodlands

26 machines, 50-odd production staff. Orders arrive as PDFs in 20 customer layouts and one person keys every line in. Revisions and due dates come over WhatsApp, across about a hundred groups. Their last software, bought on a government grant, was abandoned because it needed data entry.

A produce supplier to hotels

80 to 100 orders a week. Most arrive as PDFs from the hotels' purchasing systems, the rest as WhatsApp messages from restaurants. Six salespeople retype them into Excel. When one is on medical leave, the manager types.

"My customers must not have to change a thing."

The produce supplier's manager, her one condition for any new tool.

Nobody builds for them

Everything shipped from San Francisco and Paris assumes an IT team and software with APIs. IMDA puts SME AI adoption at 14.5%, most of it pasting into ChatGPT.

THE PRODUCT

Crosspod turns what a supplier already receives into one confirmed record the whole company works from.

- Nothing to install.** Share a Drive folder, connect a WhatsApp number or upload a chat export. Customers change nothing. Email forwarding is the next connector.
- Nine record types built for suppliers.** Sales orders, clients, items, suppliers, supplier orders, specifications, conversations, meetings, files. Read out of PDFs, scans and chats.
- Every record cites its source.** A record starts as a proposal, each line pointing at the passage it was read from. A person confirms it, and every confirmation is logged: who, when, and whether it was one record, a batch, or the extractor itself.
- Five nightly checks.** A source that changed under a record. An order untouched for 14 days. Something

mentioned often with no record. A reference to a record that does not exist. Two sources that disagree.

- Ask it.** Questions are answered from confirmed records, with the passages cited, in the app or from Claude and ChatGPT.

THE MARKET

Revenue band, 2024	Companies	Employed
> S\$100M	4,300	1.03 M
S\$1M – S\$100M (Crosspod)	77,600	1.66 M
≤ S\$1M	276,500	0.70 M

Where Sierra stops

Sierra, valued at \$15.8 billion, opened a Singapore office in November 2025 for the 4,300 companies above S\$100M: Grab, Singtel, six-figure contracts, each set up by a forward-deployed engineer.

Where we start

The 77,600 companies below that line pay a few hundred dollars a month. Teaching a system one shop's 20 order layouts is custom work, and no \$15 billion company sends an engineer to Woodlands for it. We will. The twenty-first layout is free.

Why they stay

After two years of orders, revisions and confirmations, switching means starting the company's memory over.

LESSONS FROM THE INDUSTRY

In September one of us went to AGNTCon and MCPCon Europe in Amsterdam, then AI Engineer Paris, to meet the teams building context layers for companies.

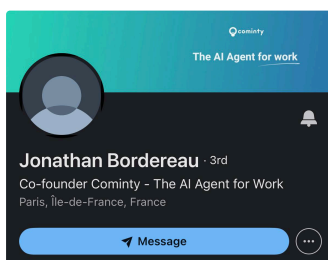

Amsterdam, 23 Sep 2026. One of us outside Input's office with the Input team.

Input, Amsterdam. Office visit.

Ex-Lemni, Sequoia-backed, moved from customer-service agents to an AI-native email client. Their bet is ours: the context under the app is the product and the app is replaceable. They are taking Gmail first, then meetings, then all of Google Workspace, and told us enterprise-scale context is still unsolved. **We kept the design and narrowed it to one object, the order.**

Dust, Paris.

3,000-plus organisations, \$40M Series B from Sequoia in May. Connects Slack, Notion, GitHub and Salesforce; employees build agents on the shared context. **We kept one rule: shared context only works when the whole team can see and correct it, so our review queue is open to everyone with access.**

Jonathan Bordereau, co-founder, Cominty. Coffee chat, Paris, September 2026.

Cominty, Paris. Coffee chat.

Co-founder Jonathan Bordereau told us Cominty had just refocused on the context layer too. **We kept their layering: ingestion, permissions, logging and model choice stay separate. We swapped the embedding model without touching the rest.**

WHAT WE LEARNT AND CHANGED FROM THE TALKS

- **Claude and ChatGPT read the record, read-only.** 14 of 89 Amsterdam talks were about agent gateways and control planes, from AWS, Google and

Booking.com, so we plug into MCP instead of building one. At AGNTCon, Molntek's Amine Raji cited 30+ MCP vulnerabilities in 60 days and 24,008 secrets in public configs, and his open labs replay a known attack: a rogue server beside a trusted WhatsApp server makes the assistant send the chat history to an attacker. So our server has three read-only tools, and each assistant gets its own key the owner can switch off.

- **We are not just a search chat.** Warmtebouw, a Dutch heating company, checked 856 tool descriptions across 103 public MCP servers and found 97% with at least one critical flaw, such as a field name that says nothing. Its fix: AI flags patterns in real data, and a domain expert validates them before the model sees them. Crosspod works the same way: its AI proposes each record, a person confirms it, and answers come from confirmed records.
- **We aim to own one platform niche.** Input picked email and went all the way down: an editor written from scratch, 20 to 30 GB of context per inbox. They told us one well-made default serves most users. Ours is the Singapore supplier under 100 staff: every PO, revision and WhatsApp order, read into one checked record.
- **Confirmations are now logged.** OpenAI's AGNTCon talk on apps shared by people and agents asked which version of the world an agent acts on after a person edits its work. Every confirmation is now an event: one record, a batch, or the extractor itself, with who and when.
- **Every assistant gets its own identity and limits.** At AGNTCon, AuthZed showed that access follows relationships (a person opens a folder, the folder holds the file), which one role cannot express; Solo.io said every agent in production needs its own identity. Each Crosspod key reads only what its holder may see. Record links sit in Postgres beside those rules; Neo4j sells fine-grained access control only in its Enterprise edition.
- **A test set modelled on real work.** Datadog saw agents that crushed public benchmarks fail on its own code, so it tests them on real work. GitHub tests its tools with curated requests and synthetic tasks. Ours does both: a seeded Drive and WhatsApp exports, 50 labelled questions and 15 question shapes from the interviews, all synthesised to protect client data. Recall is scored nightly; a drop raises a finding.

THE ASK

Both suppliers see Crosspod next Monday. The question we are asking them is "will you pay."
